CHAPTER TWO
Comparative Advantage

After studying this chapter, you should be able to:

- Explain the mercantilists’ views on trade
- Explain how trade can be based on absolute advantage
- Understand the law of comparative advantage
- Understand the relationship between opportunity costs and relative commodity prices
- Show the basis and the gains from trade under constant costs

CHAPTER OUTLINE

2.1 Introduction
2.2 Mercantilists’ Views on Trade
2.3 Trade Based on Absolute Advantage: Adam Smith
   Case Study 2-1 Mercantilism Is Alive and Well in the Twenty-First Century
2.4 Trade Based on Comparative Advantage: David Ricardo
2.5 Gains from Trade with Comparative Advantage
2.6 Comparative Advantage with Money
2.1 INTRODUCTION

In this chapter, we examine the development of trade theory from the seventeenth century through the first part of the twentieth century. This historical approach is useful not because we are interested in the history of economic thought, as such, but because it is a convenient way of introducing the concepts and theories of international trade from the simple to the more complex and realistic.
Chapter Two Comparative Advantage

The basic questions that we seek to answer in this chapter are:

1. **What is the basis for trade** and what are the gains from trade? Presumably (and as in the case of an individual), a nation will voluntarily engage in trade only if it benefits from trade. But how are gains from trade generated? How large are the gains and how are they divided among the trading nations?

2. **What is the pattern of trade?** That is, what commodities are traded and which commodities are exported and imported by each nation?

We begin with a brief discussion of the economic doctrine known as mercantilism that prevailed during the seventeenth and eighteenth centuries. We then go on to discuss the theory of absolute advantage, developed by Adam Smith. It remained for David Ricardo, however, writing some 40 years after Smith, to truly explain the pattern and the gains from trade with his law of comparative advantage. The law of comparative advantage is one of the most important laws of economics, with applicability to nations, as well as to individuals, and useful for exposing many serious fallacies in apparently logical reasoning.

One difficulty remained. Ricardo had based his explanation of the law of comparative advantage on the labor theory of value, which was subsequently rejected. In the first part of the twentieth century, Gottfried Haberler came to Ricardo’s “rescue” by explaining the law of comparative advantage in terms of the opportunity cost theory, as reflected in production possibility frontiers or transformation curves.

For simplicity, our discussion will initially refer to only two nations and two commodities. In the appendix to this chapter, the conclusions will be generalized to trade in more than two commodities and more than two nations.

### 2.2 Mercantilists’ Views on Trade

Economics, as an organized science, originated with the publication of *The Wealth of Nations* in 1776 by Adam Smith. However, writings on international trade preceded this date in such countries as England, Spain, France, Portugal, and the Netherlands as they developed into modern national states. Specifically, during the seventeenth and eighteenth centuries a group of men (merchants, bankers, government officials, and even philosophers) wrote essays and pamphlets on international trade that advocated the economic philosophy of mercantilism.

Mercantilists maintained that the way for a nation to become rich and powerful was to export more than it imported. The resulting export surplus would then be settled by an inflow of bullion, or precious metals, primarily gold and silver. The more gold and silver a nation had, the richer and more powerful it was. Thus, the government had to do all in its power to stimulate
the nation’s exports and discourage and restrict imports (particularly the import of luxury consumption goods). However, since all nations could not simultaneously have an export surplus and the amount of gold and silver was fixed at any particular point in time, one nation could gain only at the expense of other nations. The mercantilists thus preached economic nationalism, believing that national interests were basically in conflict.

The mercantilists measured the wealth of a nation by the stock of precious metals it possessed. In contrast, today we measure the wealth of a nation by its stock of human, man-made, and natural resources available for producing goods and services. The greater this stock of useful resources, the greater the flow of goods and services to satisfy human wants, and the higher the standard of living in the nation.

There were, however, more rational reasons for the mercantilists’ desire to accumulate precious metals. Remember that mercantilists were writing primarily for their nation’s rulers and to enhance national power. With more gold, rulers could maintain larger and better armies and consolidate their power at home; improved armies and navies also made it possible for them to acquire more colonies. In addition, more gold meant more money (i.e., more gold coins) in circulation and greater business activity. Furthermore, by encouraging exports and restricting imports, the government would encourage the development of new industries and encourage national output and employment.

In any event, mercantilists advocated strict government control over all economic activity and preached economic nationalism because they believed that a nation could gain in trade only at the expense of other nations (i.e., they regarded trade as a zero-sum game). These views are important for two reasons. First, the ideas of Adam Smith, David Ricardo, and other classical economists who followed can best be understood as reactions to the mercantilists’ views on trade and on the role of government. Second, today there seems to be a resurgence of neo-mercantilism, as nations plagued by slow growth and high levels of unemployment seek to restrict imports in an effort to stimulate domestic production and employment (this is examined in detail in Chapter 6). In fact, aside from England during the period 1815–1914, no Western nation has ever been completely free of mercantilist ideas (see Case Study 2-1).

2.3 TRADE BASED ON ABSOLUTE ADVANTAGE: ADAM SMITH

Smith started with the simple truth that for two nations to voluntarily trade with each other, both nations must gain. If one nation gained nothing or lost, it would simply refuse to trade. But how does this mutually beneficial trade take place and from where do these gains from trade come?
CASE STUDY 2-1

**Mercantilism Is Alive and Well in the Twenty-First Century**

Although most nations claim to be in favor of free trade, most of them continue to impose many restrictions on international trade. Most industrial nations restrict imports of agricultural commodities, textiles, shoes, steel, and many other products in order to protect domestic employment. They also provide subsidies to some of their high-tech industries, such as computers and telecommunication, deemed essential for the international competitiveness of the nation and its future growth. Developing countries are even more protective of domestic industries. As overt protection (in the form of tariffs and quotas) has been reduced or eliminated over the years through multilateral negotiations, other less explicit types of protection (such as tax benefits and subsidies for research and development) have been increased. This is evidenced by the numerous trade disputes that have arisen over the years.

During the past few years, there have been disputes between the United States and the European Union (EU) on the latter’s prohibition of U.S. beef exports from cattle raised with hormones and on genetically modified foods; on EU preferences for banana imports from African countries at the expense of bananas from Central American plantations (owned by American business interests); on EU subsidies to Airbus Industrie for the development of its new super jumbo jet that will take sales away from the Boeing’s 747; on the tax rebates that the U.S. government provided to some exporters; and on the 30 percent tariff that the United States imposed in 2002 on imported steel. There are similarly many other trade disputes between the United States, Japan, other developed and developing countries, and among all these countries with one another. Indeed, the list of protected products is long and varied. Trade restrictions are demanded to protect domestic jobs from foreign competition and to encourage domestic high-tech industries—all classic mercantilist arguments. This proves that mercantilism, though declining, is alive and well in the twenty-first century.

**Absolute advantage**

The greater efficiency that one nation may have over another in the production of a commodity. This was the basis for trade for Adam Smith.

According to Adam Smith, trade between two nations is based on absolute advantage. When one nation is more efficient than (or has an absolute advantage over) another in the production of one commodity but is less efficient than (or has an absolute disadvantage with respect to) the other nation in producing a second commodity, then both nations can gain by each specializing in the production of the commodity of its absolute advantage and exchanging part of its output with the other nation for the commodity of its absolute disadvantage. By this process, the resources of both nations are utilized most efficiently and the output of both commodities will rise. The increase in the output of both commodities measures the gains from specialization in production available to be divided or shared between the two nations through trade.

How is absolute advantage determined?
For example, because of climatic conditions, Canada is efficient in growing wheat but inefficient in growing bananas (hothouses would have to be used). On the other hand, Nicaragua is efficient in growing bananas but inefficient in growing wheat. Thus, Canada has an absolute advantage over Nicaragua in the cultivation of wheat but an absolute disadvantage in the cultivation of bananas. The opposite is true for Nicaragua. Under these circumstances, Canada would specialize in the production of wheat (i.e., produce more than needed domestically) and exchange some of it for (surplus) bananas grown in Nicaragua. As a result, both more wheat and more bananas would be grown and consumed, and both Canada and Nicaragua would gain.

Thus, while the mercantilists believed that one nation could gain only at the expense of other nations and advocated strict government control of all economic activity and trade, Adam Smith (and the other classical economists who followed him) believed that all nations would gain from free trade and strongly advocated a policy of laissez-faire (i.e., as little government interference with the economic system as possible). Free trade would lead to the most efficient use of world resources and would maximize world welfare. There were to be only a few exceptions to the policy of laissez-faire and free trade. One of these was the protection of industries important for national defense.

In view of this belief, it seems paradoxical that today most nations impose many restrictions on the free flow of international trade. Trade restrictions are invariably rationalized in terms of national welfare. In reality, they are advocated by the few industries and their workers who benefit from the restrictions but hurt consumers, who will have to pay higher prices for competing domestic goods. These issues will be examined in detail in Part Two.

Absolute advantage can be examined with a simple numerical example. Table 2.1 shows that one hour of labor time produces six bushels of wheat in the United States but only one in the United Kingdom. On the other hand, one hour of labor time produces four yards of cloth in the United States but five in the United Kingdom. Thus, the United States is more efficient than, or has an absolute advantage over, the United Kingdom in the production of wheat, while the United Kingdom is more efficient than, or has an absolute advantage over, the United States in the production of cloth. With trade, the

<table>

<td>1</td>
</tr>
<tr>
<td>Cloth (yards/hour)</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>
United States would specialize in the production of wheat and exchange part of it for British cloth. The opposite is true for the United Kingdom.

If the United States exchanges six bushels of wheat (6W) for six yards of British cloth (6C), the United States gains 2C or saves one-half hour or 30 minutes of labor time (since the United States can only exchange 6W for 4C domestically). Similarly, the 6W that the United Kingdom receives from the United States is equivalent to or would require six hours of labor time to produce in the United Kingdom. These same six hours can produce 30C in the United Kingdom (6 hours times 5 yards of cloth per hour). By being able to exchange 6C (requiring a little over one hour to produce in the United Kingdom) for 6W with the United States, the United Kingdom gains 24C, or saves almost five hours of work.

The fact that the United Kingdom gains much more than the United States is not important at this point. What is important is that both nations can gain from specialization in production and trade. (We will see in Section 2.6 how the rate at which commodities are exchanged for one another is determined and how the gains from trade are divided among the trading nations.)

Absolute advantage, however, can explain only a very small part of world trade today, such as some of the trade between developed and developing countries. Most of world trade, especially trade among developed countries, cannot be explained by absolute advantage. It remained for David Ricardo, with the law of comparative advantage, to truly explain the basis for and the gains from trade. Indeed, absolute advantage will be seen as only a special case of the more general theory of comparative advantage.

2.4 TRADE BASED ON COMPARATIVE ADVANTAGE: DAVID RICARDO

In 1817 Ricardo published his *Principles of Political Economy and Taxation*, in which he presented the law of comparative advantage. This is one of the most important and unchallenged laws of economics, with many practical applications. In this section, we will define the law of comparative advantage and restate it with a simple numerical example. In the next section, we will prove it by demonstrating that both nations can indeed gain by each specializing in the production and exportation of the commodity of its comparative advantage.

According to the law of comparative advantage, even if one nation is less efficient than (has an absolute disadvantage with respect to) the other nation in the production of both commodities, there is still a basis for mutually beneficial trade. The first nation should specialize in the production of and export the commodity in which its absolute disadvantage is smaller (this is the commodity of its comparative advantage) and import the commodity in which its absolute disadvantage is greater (this is the commodity of its comparative disadvantage).
The statement of the law can be clarified by looking at Table 2.2. The only difference between Tables 2.2 and 2.1 is that the United Kingdom now produces only two yards of cloth per hour instead of five. Thus, the United Kingdom now has an absolute disadvantage in the production of both wheat and cloth with respect to the United States.

However, since U.K. labor is only half as productive in cloth but six times less productive in wheat with respect to the United States, the United Kingdom has a comparative advantage in cloth. On the other hand, the United States has an absolute advantage in both wheat and cloth with respect to the United Kingdom, but since its absolute advantage is greater in wheat (6:1) than in cloth (4:2), the United States has a comparative advantage in wheat.

To summarize, the U.S. absolute advantage is greater in wheat, and so the United States has a comparative advantage in wheat. The U.K. absolute disadvantage is smaller in cloth, so its comparative advantage lies in cloth. According to the law of comparative advantage, both nations can gain if the United States specializes in the production of wheat and exports some of it in exchange for British cloth. (At the same time, the United Kingdom specializes in the production and exporting of cloth.)

Note that in a two-nation, two-commodity world, once it is determined that one nation has a comparative advantage in one commodity, then the other nation must necessarily have a comparative advantage in the other commodity.

### 2.5 GAINS FROM TRADE WITH COMPARATIVE ADVANTAGE

To prove the law of comparative advantage, we must be able to show that the United States and the United Kingdom can both gain by each specializing in the production and exporting the commodity of its comparative advantage.

To start with, we know that the United States would be indifferent to trade if it received only 4C from the United Kingdom in exchange for 6W, since the United States can produce exactly 4C domestically by utilizing the resources released in giving up 6W (see Table 2.2). And the United States would certainly not trade if it received less than 4C for 6W. Similarly, the United Kingdom would be indifferent to trade if it had to give up 2C for each 1W it received from the United States, and it certainly would not trade if it had to give up more than 2C for 1W.
To show that both nations can gain, suppose the United States could exchange 6W for 6C with the United Kingdom. The United States would then gain 2C (or save one-half hour of labor time) since the United States could only exchange 6W for 4C domestically. To see that the United Kingdom would also gain, note that the 6W that the United Kingdom receives from the United States would require six hours of labor time to produce in the United Kingdom. The United Kingdom could instead use these six hours to produce 12C and give up only 6C for 6W from the United States. Thus, the United Kingdom would gain 6C or save three hours of labor time. Once again, the fact that the United Kingdom gains more from trade than the United States is not important at this point. What is important is that both nations can gain from trade even if one of them (in this case the United Kingdom) is less efficient than the other in the production of both commodities.

We can convince ourselves of this by considering a simple example from everyday life. Suppose a lawyer can type twice as fast as her secretary. The lawyer then has an absolute advantage over her secretary in both the practice of law and typing. However, since the secretary cannot practice law without a law degree, the lawyer has a greater absolute advantage or a comparative advantage in law, and the secretary has a comparative advantage in typing. According to the law of comparative advantage, the lawyer should spend all of her time practicing law and let her secretary do the typing. For example, if the lawyer earns $100 per hour practicing law and must pay her secretary $10 per hour to do the typing, she would actually lose $80 for each hour that she typed. The reason for this is that she would save $20 (since she can type twice as fast as her secretary) but forgo earning $100 in the practice of law.

Returning to the United States and the United Kingdom, we see that both nations would gain by exchanging 6W for 6C. However, this is not the only rate of exchange at which mutually beneficial trade can take place. Since the United States could exchange 6W for 4C domestically (in the sense that both require 1 hour to produce), the United States would gain if it could exchange 6W for more than 4C from the United Kingdom. On the other hand, in the United Kingdom 6W = 12C (in the sense that both require 6 hours to produce). Anything less than 12C that the United Kingdom must give up to obtain 6W from the United States represents a gain from trade for the United Kingdom. To summarize, the United States gains to the extent that it can exchange 6W for more than 4C from the United Kingdom. The United Kingdom gains to the extent that it can give up less than 12C for 6W from the United States. Thus, the range for mutually advantageous trade is

$$4C < 6W < 12C$$

The spread between 12C and 4C (i.e., 8C) represents the total gains from trade available to be shared by the two nations by trading 6W. For example, we have seen that when 6W are exchanged for 6C, the United States gains 2C and the United Kingdom 6C, making a total of 8C. The closer the rate of
exchange is to $4C = 6W$ (the domestic, or internal, rate in the United States—see Table 2.2), the smaller is the share of the gain going to the United States and the larger is the share of the gain going to the United Kingdom. On the other hand, the closer the rate of exchange is to $6W = 12C$ (the domestic, or internal, rate in the United Kingdom), the greater is the gain of the United States relative to that of the United Kingdom.

For example, if the United States exchanged 6W for 8C with the United Kingdom, both nations would gain 4C, for a total gain of 8C. If the United States could exchange 6W for 10C, it would gain 6C and the United Kingdom only 2C. (Of course, the gains from trade are proportionately greater when more than 6W are traded.) In Section 2.10 we will see how this rate of exchange is actually determined in the real world by demand as well as supply considerations. The rate of exchange will also determine how the total gains from trade are actually shared by the trading nations. Up to this point, all we have wanted to do was to prove that mutually beneficial trade can take place even if one nation is less efficient than the other in the production of both commodities.

Only if the absolute disadvantage that one nation has with respect to another nation is the same in both commodities, there will be no comparative advantage and no trade. For example, if one hour of labor time produced 3W instead of 1W in the United Kingdom (see Table 2.2), the United Kingdom would be exactly half as productive as the United States in both wheat and cloth. Then the United Kingdom would not be willing to give up more than 4C to obtain 6W from the United States because the United Kingdom can produce either 6W or 4C with two hours of work domestically. Under these circumstances, no mutually beneficial trade can take place. This situation, however, would be quite coincidental and rare.

### 2.6 COMPARATIVE ADVANTAGE WITH MONEY

According to the law of comparative advantage (and disregarding the exception noted earlier), even if one nation (the United Kingdom in this case) has an absolute disadvantage in the production of both commodities with respect to the other nation (the United States), there is still a basis for mutually beneficial trade. But how, you may ask, can the United Kingdom export anything to the United States if it is less efficient than the United States in the production of both commodities? The answer is that wages in the United Kingdom will be sufficiently lower than wages in the United States so as to make the price of cloth (the commodity in which the United Kingdom has a comparative advantage) lower in the United Kingdom, and the price of wheat lower in the United States when both commodities are expressed in terms of the currency of either nation. Let us see how this works.

Suppose that the wage rate in the United States is $6 per hour. Since one hour of labor time produces 6W in the United States (see Table 2.2),
the price of a bushel of wheat is $P_w = 1$. On the other hand, since one hour of work produces 4C, $P_c = 1.50$ (from $6/4C$). Suppose that at the same time the wage rate in England is £1 per hour (the symbol “£” stands for pound, the U.K. currency). Since one hour produces 1W in the United Kingdom (see Table 2.2), $P_w = £1$ in the United Kingdom. Similarly, since one hour produces 2C, $P_c = £0.5$. If the exchange rate between the pound and the dollar is £1 = $2, then $P_w = £1 = $2$ and $P_c = £0.5 = $1$ in the United Kingdom. Table 2.3 shows the dollar price of wheat and cloth in the United States and the United Kingdom at the exchange rate of £1 = $2.

From Table 2.3 we can see that the dollar price of wheat (the commodity in which the United States has a comparative advantage) is lower in the United States than in the United Kingdom. On the other hand, the dollar price of cloth (the commodity in which the United Kingdom has a comparative advantage) is lower in the United Kingdom. (The result would be similar if the price of both commodities had been expressed in pounds.)

With the dollar price of wheat lower in the United States, businesspeople would buy wheat there and sell it in the United Kingdom, where they would buy cloth to sell in the United States. Even though U.K. labor is half as productive as U.S. labor in cloth production (see Table 2.2), U.K. labor receives only one-third of the U.S. wage rate (£1 = $2 as opposed to $6 in the United States), so that the dollar price of cloth is lower in the United Kingdom. To put it differently, the inefficiency of U.K. labor relative to U.S. labor in cloth production is more than compensated for by the lower wages in the United Kingdom. As a result, the dollar price of cloth is less in the United Kingdom, so that the United Kingdom can export cloth to the United States. This is always the case as long as the U.K. wage rate is between one-sixth and one-half of the U.S. wage rate (the same as the productivity difference between the United Kingdom and the United States in the production of wheat and cloth).

Thus, the argument that could be advanced in the United States that it needs to protect the high wages and standard of living of its workers against cheap British labor is generally false. Similarly faulty is the opposing argument that could be advanced in the United Kingdom that its labor needs protection against more efficient U.S. labor. These arguments are certainly inconsistent, and both are basically false (see Case Study 2-2).

CASE STUDY 2-2

The Petition of the Candlemakers

Sometimes satire and ridicule are more effective than theory and logic in influencing public opinion. For example, exasperated by the spread of protectionism under the prevailing mercantilist philosophy of the time, French economist Frédéric Bastiat (1801–1851) overwhelmed the proponents of protectionism by satirically extending their arguments to their logical and absurd conclusions. Nowhere is this more brilliantly accomplished than in the fictitious petition of the French candlemakers, written by Bastiat in 1845, and excerpted as follows.

We are suffering from the intolerable competition of a foreign rival, placed, it would seem, in a condition so far superior to ours for the production of light, that he absolutely inundates our national market at a price fabulously reduced. The moment he shows himself, our trade leaves us—all of our consumers apply to him; and a branch of native industry, having countless ramifications, is all at once rendered completely stagnant. This rival...is not other than the sun.

What we pray for is, that it may please you to pass a law ordering the shutting up of all windows, sky-lights, dormerwindows, curtains, blinds, bull’s eyes; in a word all openings, holes, chinks, clefts, and fissures, by or through which the light of the sun has been in use to enter houses, to the prejudice of the meritorious manufactures with which we flatter ourselves we have accommodated our country—a country which, in gratitude, ought not to abandon us now to a strife so unequal...

Does it not argue to the greatest inconsistency to check as you do the importation of coal, iron, cheese, and goods of foreign manufacture, merely because and even in proportion as their price approaches zero, while at the same time you freely admit, and without limitation, the light of the sun, whose price is during the whole day at zero?

If you shut up as much as possible all access to natural light, and create a demand for artificial light, which of our French manufactures will not be encouraged by it? If more tallow is consumed, then there must be more oxen and sheep; and, consequently, we shall behold the multiplication of artificial meadows, meat, wool, hides, and above all, manure, which is the basis and foundation of all agricultural wealth.

2.7 COMPARATIVE ADVANTAGE AND OPPORTUNITY COSTS

Ricardo based his law of comparative advantage on the labor theory of value, which postulates that the value or price of a commodity depends exclusively on the amount of labor going into the production of the commodity. This implies (1) that either labor is the only factor of production or that labor is used in the same fixed proportion in the production of all commodities and (2) that labor is homogeneous (i.e., of only one type). Since neither of these
assumptions is true, the explanation of comparative advantage should not be based on the labor theory of value.

Specifically, labor is not the only factor of production, nor is it used in the same fixed proportion in the production of all commodities. For example, much more capital equipment per worker is required to produce some products (such as steel) than to produce other products (such as textiles). In addition, there is usually some possibility of substitution between labor, capital, and other factors in the production of most commodities. Furthermore, labor is obviously not homogeneous but varies greatly in training, productivity, and wages. At the very least, we should allow for different productivities of labor. Indeed, this is how the Ricardian theory of comparative advantage has been tested and confirmed empirically (see Case Study 2–3).

The theory of comparative advantage, however, need not be based on the labor theory of value, but can be explained on the basis of the opportunity cost theory (which is acceptable). It was left to Haberler in 1936 to explain or base the theory of comparative advantage on the opportunity cost theory. In this form, the law of comparative advantage is sometimes referred to as the law of comparative cost.

According to the opportunity cost theory, the cost of a commodity is the amount of a second commodity that must be given up to release just enough resources to produce one additional unit of the first commodity. No assumption is made here that labor is the only factor of production or that labor is homogeneous. Nor is it assumed that the cost or price of a commodity depends on or can be inferred exclusively from its labor content. Consequently, the nation with the lower opportunity cost in the production of a commodity has a comparative advantage in that commodity (and a comparative disadvantage in the second commodity).

For example, since the United States must give up two-thirds of a unit of cloth to release just enough resources to produce one additional unit of wheat domestically, the opportunity cost of wheat is two-thirds of a unit of cloth (i.e., \(1W = \frac{2}{3}C\) in the United States). If \(1W = 2C\) in the United Kingdom, then the opportunity cost of wheat (in terms of the amount of cloth that must be given up) is lower in the United States than in the United Kingdom, and the United States would have a comparative (cost) advantage over the United Kingdom in wheat. In a two-nation, two-commodity world, the United Kingdom would then have a comparative advantage in cloth.

According to the law of comparative advantage, the United States should specialize in producing wheat and export some of it in exchange for British cloth. This is exactly what we concluded earlier with the law of comparative advantage based on the labor theory of value, but now our explanation is based on the opportunity cost theory.
CASE STUDY 2-3

**Labor Productivities and Comparative Advantage**

The first empirical test of the theory of comparative advantage based on labor productivities and costs was conducted by MacDougall in 1951 and 1952, using labor productivity and export data for 25 industries in the United States and the United Kingdom for the year 1937. Since wages were twice as high in the United States as in the United Kingdom, MacDougall argued that costs of production would be lower in the United States in those industries where American labor was more than twice as productive as British labor. These would be the industries in which the United States had a comparative advantage with respect to the United Kingdom and in which it would undersell the United Kingdom in the rest of the world. On the other hand, the United Kingdom would have a comparative advantage and undersell the United States in those industries where the productivity of British labor was more than one-half as productive as American labor. MacDougall’s empirical results showed that this was indeed true for 20 out of the 25 industries that he studied.

The positive relationship between labor productivity and exports for the United States and the United Kingdom was confirmed by subsequent studies by Balassa using 1950 data and Stern using 1950 and 1959 data. More recently, the Ricardian trade model was confirmed by Golub for trade between the United States and Japan using 1990 data for 33 industries and by Golub and Hsieh for trade between the United States and nine other countries (Japan, Germany, the United Kingdom, France, Italy, Canada, Australia, Mexico, and Korea) using data for 39 sectors from 1972 to 1991. Thus, production costs other than labor costs, demand considerations, political ties, and various obstructions to the flow of international trade did not seem to break the link between relative labor productivity and export shares.

2.8 PRODUCTION POSSIBILITY FRONTIER WITH CONSTANT COSTS

Opportunity costs can be illustrated with the production possibility frontier, or transformation curve. The production possibility frontier is a curve that shows the alternative combinations of the two commodities that a nation can produce by fully utilizing all of its resources with the best technology available to it.

Table 2.4 gives the (hypothetical) production possibility schedules of wheat (in million bushels/year) and cloth (in million yards/year) for the United States and the United Kingdom. We see that the United States can produce 180W and 0C, 150W and 20C, or 120W and 40C, down to 0W and 120C. For each 30W that the United States gives up, just enough resources are released to produce an additional 20C. That is, 30W = 20C (in the sense that both require the same amount of resources). Thus, the opportunity cost of one unit of wheat in the United States is \( \frac{1}{3} \)W = \( \frac{2}{3} \)C (the same as in Table 2.2) and remains constant. On the other hand, the United Kingdom can produce 60W and 0C, 50W and 20C, or 40W and 40C, down to 0W and 120C. The United Kingdom can increase its output by 20C for each 10W it gives up. Thus, the opportunity cost of wheat in the United Kingdom is \( \frac{1}{5} \)W = \( \frac{2}{5} \)C and remains constant.

The United States and United Kingdom production possibility schedules given in Table 2.4 are graphed as production possibility frontiers in Figure 2.1. Each point on a frontier represents one combination of wheat and cloth that the nation can produce. For example, at point A, the United States produces 90W and 60C. At point A’, the United Kingdom produces 40W and 40C.

Points inside, or below, the production possibility frontier are also possible but are inefficient, in the sense that the nation either has some idle resources and/or is not using the best technology available to it. On the other hand, points above the production frontier cannot be achieved with the resources and technology currently available to the nation.

The downward, or negative, slope of the production possibility frontiers in Figure 2.1 indicates that if the United States and the United Kingdom want to produce more wheat, they must give up some of their cloth production. The fact that the production possibility frontiers of both nations are straight lines reflects the fact that their opportunity costs are constant. That is, to produce each additional 1W, the United States must give up \( \frac{2}{3} \)C and the United Kingdom must give up 2C, no matter from which point on its production possibility frontier each nation starts.
FIGURE 2.1. The Production Possibility Frontiers of the United States and the United Kingdom.

The U.S. and U.K. production frontiers are obtained by plotting the values in Table 2.4. The frontiers are downward, or negatively sloped, indicating that as each nation produces more wheat, it must give up some cloth. Straight-line production possibility frontiers reflect constant opportunity costs.

Constant opportunity costs arise when (1) resources or factors of production are either perfect substitutes for each other or used in fixed proportion in the production of both commodities, and (2) all units of the same factor are homogeneous or exactly of the same quality. Then, as each nation transfers resources from the production of cloth to the production of wheat, it will not have to use resources that are less and less suited to wheat production, no matter how much wheat it is already producing. The same is true for the production of more cloth. Thus, we have constant costs in the sense that the same amount of one commodity must be given up to produce each additional unit of the second commodity.

While opportunity costs are constant in each nation, they differ among nations, providing the basis for trade. Constant costs are not realistic, however. They are discussed only because they serve as a convenient introduction to the more realistic case of increasing costs, discussed in the next chapter.

2.9 OPPORTUNITY COSTS AND RELATIVE COMMODITY PRICES

We have seen that the opportunity cost of wheat is equal to the amount of cloth that the nation must give up to release just enough resources to produce
one additional unit of wheat. This is given by the (absolute) slope of the production possibility frontier, or transformation curve, and is sometimes referred to as the marginal rate of transformation.

Figure 2.1 shows that the (absolute) slope of the U.S. transformation curve is $\frac{120}{180} = \frac{2}{3}$, the opportunity cost of wheat in the United States, and remains constant. The slope of the U.K. transformation curve is $\frac{120}{60} = 2$, the opportunity cost of wheat in the United Kingdom, and remains constant. On the assumptions that prices equal costs of production and that the nation does produce both some wheat and some cloth, the opportunity cost of wheat is equal to the price of wheat relative to the price of cloth ($\frac{P_w}{P_c}$).

Thus, $\frac{P_w}{P_c} = \frac{2}{3}$ in the United States, and inversely $\frac{P_c}{P_w} = \frac{3}{2} = 1.5$. In the United Kingdom, $\frac{P_w}{P_c} = 2$, and $\frac{P_c}{P_w} = \frac{1}{2}$. The lower $\frac{P_w}{P_c}$ in the United States ($\frac{2}{3}$ as opposed to 2 for the United Kingdom) is a reflection of the U.S. comparative advantage in wheat. Similarly, the lower $\frac{P_c}{P_w}$ in the United Kingdom ($\frac{1}{2}$ as opposed to the United States $\frac{2}{3}$) reflects the U.K. comparative advantage in cloth. Note that under constant costs, $\frac{P_w}{P_c}$ is determined exclusively by production, or supply, considerations in each nation. Demand considerations do not enter at all in the determination of relative commodity prices.

To conclude, we can say that the difference in relative commodity prices between the two nations (given by the difference in the slope of their transformation curves) is a reflection of their comparative advantage and provides the basis for mutually beneficial trade.

### 2.10 BASIS FOR AND GAINS FROM TRADE UNDER CONSTANT COSTS

In the absence of trade, a nation can only consume the commodities that it produces. As a result, the nation’s production possibility frontier also represents its consumption frontier. Which combination of commodities the nation actually chooses to produce and consume depends on the people’s tastes, or demand considerations.

For example, in the absence of trade, the United States might choose to produce and consume combination $A$ (90W and 60C) on its production possibility frontier (see Figure 2.2), and the United Kingdom might choose combination $A'$ (40W and 40C).

With trade possible, the United States would specialize in the production of wheat (the commodity of its comparative advantage) and produce at point $B$ (180W and 0C) on its production possibility frontier. Similarly, the United Kingdom would specialize in the production of cloth and produce at $B'$ (0W and 120C). If the United States then exchanges 70W for 70C with the United Kingdom, it ends up consuming at point $E$ (110W and 70C), and the United Kingdom ends up consuming at $E'$ (70W and 50C). Thus, the United States gains 20W and 10C from trade (compare point $E$ with point $A$ in
FIGURE 2.2. The Gains from Trade.
In the absence of trade, the United States produces and consumes at $A$, and the United Kingdom at $A'$. With trade, the United States specializes in the production of wheat and produces at $B$, while the United Kingdom specializes in the production of cloth and produces at $B'$. By exchanging 70W for 70C with the United Kingdom, the United States ends up consuming at $E$ (and gains 20W and 10C), while the United Kingdom ends up consuming at $E'$ (and gains 30W and 10C).

Figure 2.2), and the United Kingdom gains 30W and 10C (compare point $A'$ with point $E'$).

The increased consumption of both wheat and cloth in both nations was made possible by the increased output that resulted as each nation specialized in the production of the commodity of its comparative advantage. That is, in the absence of trade, the United States produced 90W and the United Kingdom 40W, for a total of 130W. With specialization in production and trade, 180W are produced (all in the United States). Similarly, in the absence of trade, the United States produced 60C and the United Kingdom 40C, for a total of 100C. With specialization in production and trade, 120C are produced (all in the United Kingdom).

It is this increase in output of 50W and 20C resulting from specialization in production that is shared by the United States and the United Kingdom and represents their gains from trade. Recall that in the absence of trade, the United States would not specialize in the production of wheat because it also wanted to consume some cloth. Similarly, the United Kingdom would not specialize in the production of cloth in the absence of trade because it also wanted to consume some wheat.

Note that with 70W exchanged for 70C, $P_w/P_c = 1$. At $P_w/P_c > 1$, the United States would want to export more wheat than the United Kingdom.
wants to import at that high price of wheat, and \( P_w/P_c \) would fall to 1. On the other hand, if \( P_w/P_c < 1 \), the United States would want to export less wheat than the United Kingdom would like to import at that low price of wheat, and so \( P_w/P_c \) would rise to 1. At \( P_w/P_c = 1 \) the amount of wheat that the United States wants to export is exactly equal to the amount of wheat that the United Kingdom would like to import at that price. Thus, \( P_w/P_c = 1 \) is the equilibrium relative commodity price with trade.

Finally, note that with constant costs, there is complete specialization in production in both countries, and the equilibrium-relative commodity price of each commodity is between the pretrade relative commodity price in each nation. The only exception arises if one of the two countries is too small to be able to satisfy the other nation’s demand for the small country’s export commodity. In that case, only the small nation will specialize completely, and trade will take place at the pretrade relative commodity prices in the large country. All of the gains from trade will then go to the small country. This is the small-country case and shows “the importance of being unimportant.” (This benefit, however, is not without cost since the small nation faces the risk of a possible future reduction in demand for the only commodity it produces.) What happens here is that the large nation will gain from specialization and trade with other large nations, and the small nation “just rides along.”

**SUMMARY**

1. This chapter examined the development of trade theory from the mercantilists to Smith, Ricardo, and Haberler and sought to answer two basic questions: (a) What is the basis for and what are the gains from trade? (b) What is the pattern of trade?

2. The mercantilists believed that a nation could gain in international trade only at the expense of other nations. As a result, they advocated restrictions on imports, incentives for exports, and strict government regulation of all economic activities.

3. According to Adam Smith, trade is based on absolute advantage and benefits both nations. (The discussion assumes a two-nation, two-commodity world.) That is, when each nation specializes in the production of the commodity of its absolute advantage and exchanges part of its output for the commodity of its absolute disadvantage, both nations end up consuming more of both commodities. Absolute advantage, however, explains only a small portion of international trade today.

4. David Ricardo introduced the law of comparative advantage. This postulates that even if one nation is less efficient than the other nation in the production of both commodities, there is still a basis for mutually beneficial trade. The less efficient nation should specialize in the production and export of the commodity in which its absolute disadvantage is less. This is the commodity of its comparative advantage. Ricardo, however, explained...
the law of comparative advantage in terms of the labor theory of value, which is unacceptable. Despite this, the Ricardian trade model is confirmed empirically when expressed in terms of relative labor productivities.

5. Gottfried Haberler came to the “rescue” by explaining the law of comparative advantage in terms of the opportunity cost theory. This states that the cost of a commodity is the amount of a second commodity that must be given up in order to release just enough resources to produce one additional unit of the first commodity. The opportunity cost of a commodity is equal to the relative price of that commodity and is given by the (absolute) slope of the production possibility frontier. A straight-line production possibility frontier reflects constant opportunity costs.

6. In the absence of trade, a nation’s production possibility frontier is also its consumption frontier. With trade, each nation can specialize in producing the commodity of its comparative advantage and exchange part of its output for the commodity of its comparative disadvantage from the other nation. By so doing, both nations end up consuming more of both commodities than without trade. With complete specialization, the equilibrium-relative commodity prices will be between the pretrade-relative commodity prices prevailing in each nation.

**REVIEW QUESTIONS AND PROBLEMS**

1. What were the mercantilists’ views on trade? How were their views different from those of Adam Smith? What is the relevance of all this today?

2. What was the basis for and the pattern of trade according to Adam Smith? How were gains from trade generated? What policies did Smith advocate in international trade? What did he think was the proper function of government in the economic life of the nation?

3. In what way was Ricardo’s law of comparative advantage superior to Smith’s theory of absolute advantage? How do gains from trade arise with comparative advantage? How can a nation that is less efficient than another nation in the production of all commodities export anything to the second nation?

4. Table 2.5, on page 51, shows bushels of wheat and the yards of cloth that the United States and the United Kingdom can produce with one hour of labor time under four different hypothetical situations. In each case, identify the commodity in which the United States and the United Kingdom have
   (a) an absolute advantage or disadvantage.
   (b) comparative advantage or disadvantage.

5. Suppose that, in Case B in Table 2.5, the United States exchanges 4W for 4C with the United Kingdom.
   (a) How much does the United States gain in terms of C?
   (b) How much does the United Kingdom gain in terms of C?
   (c) What is the range for mutually beneficial trade?
Table 2.5. Production Possibilities in the United States and the United Kingdom

</tbody>
</table>

(d) How much would each nation gain in terms of C if they exchanged 4W for 6C instead?

6. Using the information for Case B in Table 2.5, assume that labor is the only factor of production and is homogeneous (i.e., all of one type).
   (a) What is the cost in terms of labor content of producing wheat and cloth in the United States and the United Kingdom?
   (b) What is the dollar price of wheat and cloth in the United States if the wage rate is $6?
   (c) What is the pound price of wheat and cloth in the United Kingdom if the wage rate is £1?

7. How would you counter the argument that the United States needs to restrict textile imports in order to save American jobs?

8. Why is Ricardo’s explanation of the law of comparative advantage unacceptable? What acceptable theory can be used to explain the law?

9. What is the relationship between opportunity costs and the production possibility frontier of a nation? How does the production possibility frontier look under constant opportunity costs? What is the relationship between the opportunity cost of a commodity and the relative price of that commodity? How can they be visualized graphically?

10. Assume that the data in Case B in Table 2.5 refer to millions of bushels of wheat and of yards of cloth.
    (a) Plot on graph paper the production frontiers of the United States and the United Kingdom.
    (b) What is the relative price of wheat (i.e., $P_w/P_c$) in the United States and in the United Kingdom under autarky (no trade)?
    (c) What is the relative price of cloth (i.e., $P_c/P_w$) in the United States and in the United Kingdom under autarky (no trade)?
    (d) Assuming that the no-trade or autarky point is 3W and 3/4C (in million units) in the United States and 1/2W and 1C in the United Kingdom. Assuming also that with the opening of trade the United States exchanges 1W for 1C with the United Kingdom. Show graphically for the United States and the United Kingdom the autarky (or no-trade) point of production and consumption, the point of production and consumption with trade, and the gains from trade.
We now extend the theory of comparative advantage first to the case of more than two commodities and then to the case of more than two nations. In each case, we will see that the theory of comparative advantage is easily generalized.

### A2.1 COMPARATIVE ADVANTAGE WITH MORE THAN TWO COMMODITIES

Table 2.6 shows the dollar and the pound cost, or price, of five commodities in the United States and the United Kingdom.

To determine which commodities will be exported and imported by the United States and the United Kingdom, we must first express all commodity prices in terms of the same currency and then compare prices in the two nations. For example, if the exchange rate between the dollar and the pound is £1 = $2, the dollar prices of the commodities in the United Kingdom are:

<table>
<thead>
<tr>
<th>Commodity</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dollar price in the U.K.</td>
<td>12</td>
<td>8</td>
<td>6</td>
<td>4</td>
<td>2</td>
</tr>
</tbody>
</table>
Table 2.6. Commodity Prices in the United States and United Kingdom

<table>
<thead>
<tr>
<th>Commodity</th>
<th>Price in the U.S.</th>
<th>Price in the U.K.</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>$2</td>
<td>£6</td>
</tr>
<tr>
<td>B</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>C</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>D</td>
<td>8</td>
<td>2</td>
</tr>
<tr>
<td>E</td>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>

At this exchange rate, the dollar prices of commodities A and B are lower in the United States than in the United Kingdom; commodity C is equally priced in the two nations; and the dollar prices of commodities D and E are lower in the United Kingdom. As a result, the United States will export commodities A and B to the United Kingdom and import commodities D and E from the United Kingdom. Commodity C will not be traded.

Now assume that the exchange rate between the dollar and the pound is £1 = $3. The dollar price of the commodities in the United Kingdom would be:

<table>
<thead>
<tr>
<th>Commodity</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dollar price in the U.K.</td>
<td>18</td>
<td>12</td>
<td>9</td>
<td>6</td>
<td>3</td>
</tr>
</tbody>
</table>

At this higher exchange rate, the dollar prices of commodities A, B, and C are lower in the United States, while the dollar prices of commodities D and E are lower in the United Kingdom. Thus, the United States would export commodities A, B, and C to the United Kingdom and import commodities D and E from the United Kingdom. Note that commodity C, which was not traded at the exchange rate of £1 = $2, is now exported by the United States at the exchange rate of £1 = $3.

Finally, if the exchange rate were £1 = $1, the dollar prices of the commodities in the United Kingdom would be:

<table>
<thead>
<tr>
<th>Commodity</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dollar price in the U.K.</td>
<td>6</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

In this case, the United States would export only commodity A to the United Kingdom and import all other commodities, with the exception of commodity B (which would not be traded because it is now equally priced in the two nations).

If the exchange rate between the dollar and the pound is flexible and is determined exclusively by trade forces, then the actual exchange rate
between the dollar and the pound will settle at the level at which the value of U.S. exports to the United Kingdom exactly equals the value of the U.S. imports from the United Kingdom. Once this equilibrium exchange rate is established, we will be able to determine exactly which commodities are exported by the United States and which are exported by the United Kingdom. Each nation will then have a comparative advantage in the commodities that it exports at the particular equilibrium exchange rate established.

What we can say on the basis of Table 2.6 is that the U.S. comparative advantage is greatest in commodity A, and the United States must export at least this commodity. For this to be possible, the exchange rate between the dollar and the pound must be £1 > $0.33. The United Kingdom’s comparative advantage is highest in commodity E, so that the United Kingdom must export at least commodity E. For this to be possible, the exchange rate between the dollar and the pound must be £1 < $10. This discussion can be generalized to cover any number of commodities.

**A2.2 COMPARATIVE ADVANTAGE WITH MORE THAN TWO NATIONS**

Suppose that, instead of two nations and five commodities, we have two commodities (wheat and cloth) and five nations (A,B,C,D, and E). Table 2.7 ranks these nations from lowest to highest in terms of their internal \( P_w/P_c \) values. With trade, the equilibrium \( P_w/P_c \) will settle somewhere between 1 and 5. That is, \( 1 < P_w/P_c < 5 \).

If the equilibrium \( P_w/P_c = 3 \) with trade, Nations A and B will export wheat to Nations D and E in exchange for cloth. Nation C will not engage in international trade in this case because its pretrade \( P_w/P_c \) equals the equilibrium \( P_w/P_c \) with trade. Given a trade equilibrium \( P_w/P_c = 4 \), Nations A, B, and C will export wheat to Nation E in exchange for cloth, and Nation D will not engage in international trade. If the equilibrium \( P_w/P_c = 2 \) with trade, Nation A will export wheat to all the other nations, with the exception of Nation B, in exchange for cloth.

This discussion can easily be extended to any number of countries and commodities. Thus, the conclusions reached on the basis of our simple model with only two nations and two commodities can be generalized and are applicable to the case of many nations and many commodities.

**Table 2.7. Ranking of Nations in Terms of Internal Pw/Pc**
